| Part I | Exploring and Understanding Data |
|---------------------------------|---|
| Chapter 1 | Stats Starts Here |
| Statistics is | a way of reasoning, along with a collection of tools and methods, |
| | designed to help us understand the world. |
| Statistics are | particular calculations made from data. |
| A statistic is | A numerical summary of data |
| Statistics is about | variation |
| Chapter 2 | Data |
| Data are | values along with their context |
| The context for data values is | The "W's" |
| provided by | Why do we care about the data? |
| | Who are the individuals described by the data? |
| | What variables do the data contain? |
| | When |
| | Where |
| | How |
| | (Necessary) |
| Three steps to doing Statistics | Think –were you're headed and why (the "W's"). |
| right: | Show – the mechanics of calculating statistics and making displays. |
| | Tell – what you've learned remembering the "4 Cs." |
| 4 Cs: conclusions are | Clear, concise, complete, and in context. |
| Data table | An arrangement of data in which each row represents a case and |
| | each column represents a variable. |
| Case | An individual about whom we have data (row of data table) |
| Individual | Object described by a set of data (person, animal, thing, identifier |
| | variable) |
| Variable | Holds information about the same characteristic for many cases. |
| | (column of data table) |
| Variables can usually be | |
| identified as either or : | Categorical or quantitative |
| Categorical variable | Places an individual into one of several groups or categories |
| Quantitative variable | Has numerical values (with units) that measure some characteristic |
| | of each individual. |
| Ordinal variable | Reports order with out natural units. |
| You must look at the | Why |
| of your study to decide whether | 5 |
| to treat it as or | Categorical or quantitative |
| Identifier variable | ID number or other convention often used to protect confidentiality |
| | (Categorical variable with exactly one individual in each category) |
| Chapter 3 | Displaying and Describing Categorical Data |
| Three things you should always | 1. Make a picture – a display will help you <i>think</i> clearly about |
| do first with data: | patterns and relationships that may be hiding in your data. |
| | 2. Make a picture – <i>show</i> important features and patterns in your |
| | data |
| | 3. Make a picture – best way to <i>tell</i> others about your data. |
| To analyze categorical data, we | · · · · · |
| often use or | counts (frequencies) or percents (relative frequencies) |

| of individuals that fall into | |
|---------------------------------|--|
| various categories. | |
| (Relative) Frequency table | Lists the categories in a categorical variable and the (percentage) |
| [Distribution of a categorical | count of observations for each category. |
| variable] | |
| Area principle | In a statistical display, each data value should be represented by the |
| 1 1 | same amount of area. |
| (Relative Frequency) Bar chart | Shows a bar representing the (percentage) count of each category in |
| | a categorical variable. |
| Pie chart | Shows how a "whole" divides into categories by showing a wedge |
| | of a circle whose area corresponds to the proportion in each |
| | category. |
| Contingency table | Displays counts (percentages) of individuals falling into named |
| | categories on two (or more) variables, columns vs. rows. The table |
| | categorizes the individuals on all variables at once to reveal |
| | possible patterns in one variable that may be contingent on the |
| | category of the other |
| Marginal distribution | The distribution of one of the variables alone is seen in the totals |
| | found in the last row/column of a contingency table (see frequency |
| | table) |
| Conditional distribution | The distribution of a variable restricting the <i>Who</i> to consider only a |
| | smaller group of individuals |
| | [A single row (column) of the contingency table] |
| Relationships among | [IT single low (column) of the contingency table.] |
| categorical variables are | |
| described by calculating | narcants |
| from the given. This | counts |
| avoide | count variation between them |
| Sogmonted Bar Chart | A stacked relative frequency has chart (100% total) |
| Segmented Bar Chart | A stacked relative frequency bar chart (100% total). |
| | Is nig chart within a her chart |
| Independent verichles | The conditional distribution of one variable is the same for each |
| independent variables | The conditional distribution of one variable is the same for each |
| | category of the other. |
| <u>S'anne a 2 a marte da m</u> | [11 rows (columns) of contingency table have = distributions] |
| Simpson's paradox | when averages are taken across different groups, they can appear to |
| Character A | Contradict the overall averages |
| Chapter 4 | Displaying Quantitative Data |
| Distribution of a quantitative | Tells us what values a variable takes and how often it takes them. |
| variable | Snows the pattern of variation of a (quantitative) variable. |
| Stem-and-leaf plot | A sideways histogram that shows the individual values. |
| | Bins/intervals might be the tens places with the ones places strung |
| | out sequentially to the right. |
| Back-to-back stem-and-leaf plot | Useful for comparing two related distributions with a moderate |
| | number of observations. |
| Dotplot | Graphs a dot for each case against a single axis. |
| (Relative Frequency) Histogram | Uses adjacent, equal-width bars to show the distribution of values in |
| | a quantitative variable. Each bar represents the (percentage) count |
| | falling in a particular interval of values. (% are useful for comparing |

| | several distributions with different numbers of observations.) |
|------------------------------------|---|
| A good estimate for how many | |
| bars will give a decent | Number of observations |
| histogram = | 5 |
| Once we make a picture, we | Shape, center, spread, and any unusual features. |
| describe a distribution by telling | |
| about its | |
| Shape | Uniform, single, multiple modes |
| | Symmetry vs. skewed |
| Uniform | A distribution that is roughly flat. |
| Mode | A hump or local high point in the shape of the distribution of a |
| | variable (unimodal, bimodal, multimodal). |
| Symmetric | A distribution where the two halves on either side of the center look |
| | approximately like mirror images of each other. |
| Skewed (left/right) | A non-symmetrical distribution where one tail stretches out further |
| | (to the left/right) than the other. |
| Center | A "typical" value that attempts the impossible, summarizing the |
| | entire distribution with a single number. {midpoint} |
| Spread | A numerical summary of how tightly the values are clustered around |
| | the "center." {range} |
| Outliers | Extreme values that don't appear to belong with the rest of the data. |
| Timeplot | Displays quantitative data collected over time (x-axis). Can reveal |
| | trends overlooked by histograms and stem-and-leaf plots that ignore |
| | time order. Often, successive values are connected with lines to |
| | show trends more clearly. |
| Time series | Measurements of a variable taken at regular time intervals. |
| Seasonal variation | A pattern in a time series that repeats itself at know regular intervals |
| | of time. |
| Chapter 5 | Describing Distributions Numerically |
| Median | Middle value (balances data by counts) (equal-areas point) |
| Range | Max – min data values |
| <i>p</i> th percentile | Value such that <i>p</i> percent of the observations fall at or below it. |
| Lower quartile (Q1) | Median of the lower half. (25 th percentile) |
| Upper quartile (Q3) | Median of the upper half. (75 th percentile) |
| Interquartile range (IQR) | Q3 - Q1, the middle half of the data. |
| 5-number summary | Max |
| | Q3 |
| | Median |
| | Q1 |
| | Min |
| Suspected outlier | If observation $>$ Q3 + (1.5)(IQR) |
| | Or observation $<$ Q1 – (1.5)(IQR) |
| Boxplot | Displays the 5-number summary as a central box with whiskers that |
| | extend to the non-outlying data values. Particularly effective for |
| | comparing groups. However, a histogram or stem-and-leaf plot is a |
| | clearer display of the shape of a distribution. |
| Mean | [Average] |

| | $\overline{x} = \frac{\sum x}{\sum x}$ |
|---------------------------------|--|
| | |
| | Add up all the numbers and divide by n (balance point, by size) (balances deviations) |
| Deviation | How far each data value is from the mean |
| Variance | $\frac{\sum (x - \overline{x})^2}{\sum (x - \overline{x})^2}$ |
| v ununee | $s^2 = \frac{\sum (x-x)}{x}$ |
| | n-1 |
| Chan dand dariation | Sum of the squared deviations from the mean, divided by $n - 1$. |
| Standard deviation | $s = \sqrt{\frac{\sum (x - \overline{x})^2}{n - 1}}$ |
| | The square root of the variance (gets us back to the original units) |
| Report summary statistics to | 1 0 |
| decimal places | 1 or 2 |
| When describing the | more man the original data. |
| distribution of a quantitative | |
| variable if the shape is skewed | |
| then report | median and IOR (they are based on position) |
| If the shape is symmetric then | incutant and IQIX (they are based on position) |
| report and | mean and standard deviation (they are based on size/value) |
| repeat calculations without | |
| if present. | outliers |
| A complete analysis of data | |
| almost always includes: | Verbal, visual, and numerical summaries. |
| Answers are, not | sentences, numbers |
| Chapter 6 | The Standard Deviation as a Ruler and the Normal Model |
| Adding (subtracting) a constant | |
| to every data value | adds (subtracts) |
| the same constant to measures | |
| of position/center and | 1 / 1 |
| measures of spread. | does not change |
| deta value by a constant | |
| the same constant | multiplies (divides) |
| to measures of position/center | multiplies (urvides) |
| and measures of | multiplies (divides) |
| spread. | |
| Changing the center and spread | |
| of a variable is equivalent to | changing its units. |
| Standardizing | Uses the standard deviation as a ruler to measure distance from the |
| | mean creating z-scores |
| | $z = \frac{(x - \overline{x})}{\overline{x}}$ |
| | <i>z</i> – <i>S</i> |
| z-scores tell us | the number of standard deviations a value is from the mean. |
| important uses are: | 1. Comparing values from different distributions (decathlon events) |
| | or values based on different units. |

| | 2. Identifying unusual or surprising values among data. |
|-------------------------------------|---|
| | 3. |
| | |
| Units can be eliminated by | standardizing the data. |
| have no units. | z-scores |
| When we standardize data to get | |
| we do two things. | z-scores |
| First we the data by | shift |
| subtracting the mean. Then we | |
| the data by dividing by | rescale |
| their standard deviation. | |
| Standardizing has the following | Shape – is not changed. |
| affect on the distribution of a | Center – the mean is shifted to 0 |
| variable: | Spread – the standard deviation is rescaled to 1 |
| If the distribution of a | |
| quantitative variable is | unimodal |
| and then the we can | roughly symmetric |
| replace histograms by | |
| approximating the distribution | |
| with | a normal model. |
| are summaries of | Statistics |
| the data denoted with | Latin letters |
| mean,standard deviation, | <i>x</i> , s |
| are numerically | Parameters |
| valued attributes [statistics] of a | |
| model (they don't come from | |
| the data, they just specify the | |
| model) denoted with | Greek letters |
| mean,standard deviation, | μ, o |
| A normal model is constructed | $v = \frac{1}{1 - e^{-\frac{1}{2}(\frac{x-\mu}{\sigma})^2}}$ |
| from a rather complex equation | $y = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{1}{\sigma}}$ |
| only dependent on parameters | mean, standard deviation |
| for and | $N(\mu,\sigma)$ |
| The distribution of a all many all | |
| I ne distribution of each normal | weine del ermenetrie and hell shared |
| model is,, and | unimodal, symmetric, and ben-snaped |
| as show by its density curve. | |
| we call it a defisity curve | |
| normal model adjusts the scale | |
| (of y height) so that the area | |
| (or y, height) so that the area | 1 |
| the for the distribution | relative frequency |
| This scaling is extremely | Specifically, it allows us to convert standard deviations into percents |
| important in conceptualizing | that are much easier to comprehend |
| how unusual a value(z-score) is | |
| To avoid having to work with | we convert our data to z-scores and use just one Standard Normal |
| the complicated normal model | Model $N(0, 1)$ and its associated table |
| the complicated normal model | model mo, i) and its associated able. |

| equation or lug around a myriad | |
|-----------------------------------|---|
| of tables for every possible | |
| $N(\mu,\sigma)$ | |
| Normal percentile | Read from a table of normal probabilities, it gives the percentage of |
| | values in a standard normal distribution found lying below a |
| | particular z-score. |
| The easiest conversion (from | |
| standard deviations to percents) | |
| is to remember the | 68,95,99.7 |
| rule. About of the data fall | 68% |
| within 1 standard deviation of | |
| the mean, about within 2 | 95% |
| and about within 3. | 99.7% |
| Use this TI function | normalcdf(lower z-score, upper z-score) |
| if asked to find % or area | |
| Use this TI function | invNorm(area to left) |
| If given % or area | output is z-score that may have to be converted back |
| is a more precise | A normal probability plot |
| method than a histogram of | |
| checking the nearly normal | |
| condition, that the shape of the | |
| data's distribution is | unimodal |
| and | roughly symmetric |
| If the normal probability plot is | |
| roughly | a diagonal straight line |
| Then a normal model | |
| | will approximate the (actual) data well. |
| The of a normal | Inflection point |
| curve identifies one standard | |
| deviation from the mean. | |
| 3 reasons normal distributions | 1. Good descriptions for some distributions of real data. |
| are important in statistics: | 2. Good approximations to many kinds of chance outcomes. |
| | 3. Utilized in many statistical inference procedures. |
